## 2 Hardware

# 3 VHSIC Hardware Description Language (VHDL)

## 3.1 Basic syntax and identifiers

In VHDL an identifier is a case insensitive string composed of A–Z  $\,$  a–z  $\,$  0–9  $\,$  \_ that

- is not a keyword,
- does not start with a number or \_,
- does not have two or more \_ in a row.

Expressions are terminated by a semicolon;. Two dashes in a row cause the rest of the line to be interpreted as a comment.

```
1 expression; -- comment
```

#### 3.2 Structure and Libraries

The VHDL code is organized into *libraries* declared with the library keyword. The library of your code is called work, standard features (bit, integer, ...) are found in std, and IEEE standard parts are in ieee. work and std are always implicit and must not be declared.

```
1 library \( library name \);
```

Once declared a library is composed of *packages*, which can contain elements (constants, entities, ...). To access the elements the syntax is

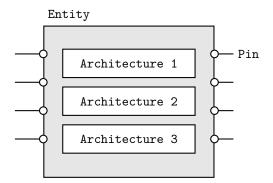

```
1 \langle library \rangle . \langle package \rangle . \langle element \rangle;
```

To avoid having to write a long name every time it is possible to import names using

```
1 use \langle library \rangle . \langle element or all \rangle;
2 use \langle library \rangle . \langle package \rangle . \langle element or all \rangle;
```

## 3.3 Entities and Architectures

In VHDL the concept of *entity* describes a black box of which only inputs and outputs are known. The internals of an entity are described through an *architecture*. There can be multiple architectures for a single entity.

Entities are declared with port() that may contain a list of pins. Pins have a mode that can be in input (only LHS<sup>1</sup>), out output (only RHS<sup>2</sup>), inout bidirectional or buffer that can stay both on LHS and RHS. The usage of the latter is discourareged in favour of an internal signal.

```
1 entity \( name \) is
2  port(
3  \( \pin \) : \( \pin de \) \( \text{type} \);
4  );
5 end \( name \);
```

Architectures are normally named after the design model, examples are behavioral, structural.

#### 3.4 Electric types

VHDL provides some types such as

- boolean true or false,
- bit 0 or 1,
- bit\_vector one dimensional array of bits,
- integer 32-bit binary representation of a value.

From external libraries other types are available:

- std\_logic advanced logic with 9 states,
- std\_ulogic same as the previous but *unresolved*.

The above are from the ieee.std\_logic\_1164 library, and can take the values described in the following table.

| Value | Meaning        | Usage                                       |  |  |  |  |
|-------|----------------|---|--|--|--|--|
| U     | Uninitialized  | In the simulator                            |  |  |  |  |
| X     | Undefined      | Simulator sees a bus conflict               |  |  |  |  |
| 0     | Force to 0     | Low state of outputs                        |  |  |  |  |
| 1     | Force to 1     | High state of outputs                       |  |  |  |  |
| Z     | High Impedance | Three state ports                           |  |  |  |  |
| W     | Weak Unknown   | Simulator sees weak a bus conflict          |  |  |  |  |
| L     | Weak Low       | Open source outputs with pull-down resistor |  |  |  |  |
| Н     | Weak High      | Open drain output with pull-up resistor     |  |  |  |  |
| -     | Don't care     | Allow minimization                          |  |  |  |  |

For the *resolved* types, i.e. std\_logic types, when a signal is multiply driven the conflict is resolved according to the table below. Unresolved types will give a synthesization error.

<sup>&</sup>lt;sup>1</sup>Left hand side

 $<sup>^2\</sup>mathrm{Right}$  hand side

|   | U | Х | 0 | 1 | Z | W | L | Н | - |
|---|---|---|---|---|---|---|---|---|---|
| U | U | U | U | U | U | U | U | U | U |
| X | U | X | X | X | X | X | X | X | X |
|   | U | X | 0 | X | 0 | 0 | 0 | 0 | X |
| 1 | U | Х | Х | 1 | 1 | 1 | 1 | 1 | X |
| Z | U | X | 0 | 1 | Z | W | L | Н | X |
| W | U | X | 0 | 1 | W | W | W | W | X |
| L | U | X | 0 | 1 | L | W | L | W | X |
| Н | U | Х | 0 | 1 | Н | W | W | Н | X |
| - | U | X | X | X | X | X | X | X | X |

A good example is a tri-state bus:

```
1 architecture tristate of buscontrol is
2 begin
    bus_read: inp <= bus_io;</pre>
3
4
5
    bus_write: process(enable, oup)
6
     begin
       bus_io <= (others => 'Z');
       if enable = '1' then
         bus_io <= oup;</pre>
9
10
       end if;
11
     end process;
12 end architecture tristateout;
```

#### 3.5 Declarations

Before a begin – end block, there is usually a list of declarations. A self evident examples are *constants*.

```
1 constant \langle name \rangle : \langle type \rangle := \langle value \rangle;
```

Next, *signals* and *variables*. Signals is are wires, they can only be connected and do not have an initial state. Variables can be assigned like in software, but can cause the synthesization of an unwanted D-Latch.

```
1 signal \langle name \rangle, [name, ...] : \langle type \rangle;
2
3 variable \langle name \rangle, [name], [...] : \langle type \rangle;
4 variable \langle name \rangle : \langle type \rangle := \langle expression \rangle;
```

For the hierarchical designs, when external entities are used, they must be declared as components. The port() expression must match the entity declaration.

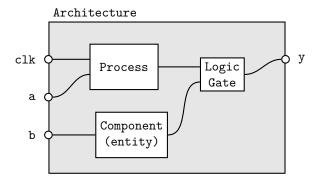

```
1 component \langle entity name \rangle is
2  port(
3  [list of pins]
4 );
5 end component;
```

For entities with multiple architectures, it is possible to choose which architecture is used with the following expression.

```
1 for \langle label \ or \ all \rangle: use entity \langle library \rangle.

\hookrightarrow \langle entity \rangle (\langle architecture \rangle);
```

#### 3.6 Concurrent Area

In the architecture between **begin** and **end**, the expressions are *not* read sequentially, everything happens at the same time. Statements inside the concurrent area optionally have a label.

```
1 [label]: \(\langle concurrent statement \rangle;\)
```

In the concurrent area signals, components and processes can be used to create a logic.

#### 3.6.1 Signal assignment and simple gates

Signals are assigned using <=.

```
1 [label]: \langle signal \rangle \leftarrow \langle expression \rangle;
```

Simple logic functions such as not, and, or, xor, etc. can be used.

```
1 y <= (a and s) or (b and not(s));</pre>
```

#### 3.6.2 Aggregates

For vector types it is possible to create a value out of multiple signals.

```
1 \langle vector \rangle <= (
2 \langle index \rangle => \langle source or value \rangle,
3 \langle index \rangle => \langle source or value \rangle,
4 [others] => \langle source or value \rangle
5 );

1 -- declaration
2 signal data : bit_vector(6 downto 0);
3 signal a, b : bit;

1 -- concurrent
2 data = (1 => a, 0 => b, others => '0')
```

#### 3.6.3 Selective and conditional assignment

Higher level conditions can be written in two ways.

```
1 -- using when
2 [label]: y <= \langle source \rangle when \langle condition \rangle else
3 \langle source \rangle when \langle condition \rangle;
4 \langle source \rangle when \langle condition \rangle;
5 \langle source \rangle when \langle value \rangle,
6 \langle source \rangle when \langle value \rangle,
7 \langle source \rangle when \langle value \rangle,
8 \langle source \rangle when \langle value \rangle,
9 \langle source \rangle when \rangle value \rangle \rangle \rangle \rangle \rangle \ra
```

#### 3.6.4 Components

External components that have been previously declared can be used with the port  $map(\langle assignments \rangle)$  syntax. For example:

```
1 -- declaration
2 component flipflop is
    port(
      clk, set, rst : in std_ulogic,
5
      Q, Qn
                 : out std_ulogic
    );
6
7 end component flipflop;
9 signal clk_int, a, b : in std_ulogic;
10 signal y, z
                       : out std_ulogic;
1 -- concurrent
2 u1: flipflop
    port map(
3
      clk => clk_int,
      set => a,
6
      rst => b,
7
      Q
          => y,
8
      Qn
          => z
9
    );
```

#### 3.6.5 Processes

For more sophisticated logic VHDL offers a way of writing sequential statements called *process*.

```
1 [label]: process ([sensitivity list])
2 -- declarations
3 begin
4 -- sequential statements
5 end process;
```

Processes have a sensitivity list that can be empty. When a signal in the sensitivity list changes state, the process is executed. With an empty sensitivity list, the process runs continuously. In the declaration, everything from §3.5 applies. For the sequential statements, the following applies:

- Neither selective (with) nor conditional (when) should be used. They are replaced with new sequential constructs (if and case).
- Signal assignments (with <=) change their value only at the end of the process.
- Variables on the other hand change as soon as they are assigned (with :=).

And for good practice:

- Before any if or case default values should be assigned.
- Any signal on the RHS should be in the sensitivity list.
- Processes with empty sensitivity lists should only be used for simulations.

The sequential replacements for with and when are in the listings below.

```
1 if \langle condition \rangle then
2 -- sequential statements
3 elsif \langle condition \rangle then
4 -- sequential statements
5 else
6
    -- sequential statements
7 end if;
1 case \langle expression \rangle is
    when \langle choice \rangle =>
3
       -- sequential statements
    when \( \choice \) =>
4
5
       -- sequential statements
    when others =>
7
       -- sequential statements
8 end case;
```

Processes can detect *attributes* of signals. Typically it is used for clocks. There are also other attributes such as s'stable(t).

```
1 process (clk)
2 begin
    -- rising edge
    if clk'event and clk = '1' then
       ... end if;
6
    if rising_edge(clk) then
7
       ... end if;
8
9
    -- falling edge
    if clk'event and clk = '0' then
10
      ... end if;
11
    if falling_edge(clk) then
12
1.3
      ... end if;
14 end process;
```

#### 3.7 Custom and arithmetic types

It is possible to create custom types, usually to create state machines.

```
1 type \( name \) is (\( identifier \), \( identifier \), \( ...);
```

#### 3.8 Pitfalls and RTL model

Coming from a programming language, a common pitfall is to write something like

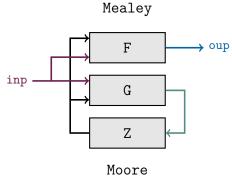

```
1 -- wrong!!!
2 y <= y xor a;
a =1
```

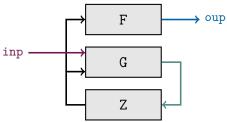

but this will be synthesised into an oscillating circuit, that must be avoided at all costs. The correct way is to have a memory for the next state, with a logic separated into combinatorial and sequential parts.

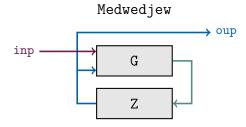

```
1 -- combinatorial
2 y_next <= y xor a;
3 -- sequential
4 process (clk)
5 begin
6   if rising_edge(clk) then
7   y <= y_next;
8   end if;
9 end process;</pre>
```

This method is known as register transfer level design.

# 4 State Machines

### 4.1 Encoding the state

For Mealey and Moore machines it is typical to write:

The encoding of the state is left to the synthesizer or can be configured in the graphical interface of the tool. If a custom encoding is required (Medwedjew), adding the following generates a custom encoding.

```
1 attribute enum_encoding : string;
2 attribute enum_encoding of state_type:
3 type is "0001 0010 0100 ...";
```

Or an equivalent approach is to use a vector subtype and constants.

## 4.2 Updating the state register (Z)

```
1 register_logic: process (clk, rst)
2 begin
     -- asynchronous reset
4
     if rst = '1' then
       present_state <= st_rst;</pre>
5
6
7
     -- clock
8
     elsif rising_edge(clk) then
9
       present_state <= next_state;</pre>
10
     end if;
11 end process;
```

## 4.3 Updating the state (G)

```
1 next_state_logic:
2 process (present_state, [inputs])
3 begin
     -- default value
     next_state <= state_rst;</pre>
5
7
     case present_state is
8
       when st_rst =>
9
          -- reset state logic
10
          next_state \lt= \langle state \rangle;
11
       when st_a =>
12
          -- logic using inputs
13
14
          next_state <= \langle state \rangle;
15
16
       when others => null;
17
     end case:
18
19 end process;
```

### 4.4 Updating the output (F)

2 process (present\_state,  $\langle inputs \rangle$ )

Mealey

3 begin

Medwedjew

1 output\_logic:

1 output\_logic: \langle output \rangle <= present\_state;</pre>

## 5 Testing

To simulate a digial circuit it is possible to write test benches using VHDL. The code in this section may no longer be synthetisable, and is usually written by a *test* designer.

#### 5.1 Simulator

VHDL simulates digital systems using delta cycles.

## 5.2 Transport delay

To model a time delay of a signal there are two ways:

```
1 y <= transport \( \langle expression \rangle \) after \( \langle time \rangle ;
2 y <= inertial \( \langle expression \rangle \) after \( \langle time \rangle ; \)</pre>
```

When transport is used, the output changes only exactly after the specified time, the simulator simply waits. With inertial, the output is also delayed, but only if the input lasts more than the specified time. This means that for example with a time of 10 ns a pulse of 5 ns will be ignored. This is much more typical and realistic, thus when unspecified, after is interpreted as inertial ... after.

```
1 y <= \langle expression \rangle after \langle time \rangle;</pre>
```

#### 5.3 Generate stimuli

Simple stimuli (signals) are generated using processes. For example a clock signal done in three ways:

```
1 -- declaration
2 constant f : integer := 1000;
3 constant T : time := 1 sec/f;
4 signal clk0, clk1, clk2 : std_ulogic;
1 -- concurrent
2 clock0: process
3 begin
   clk <= '1'; wait for (T/2);
    clk <= '0'; wait for (T/2);</pre>
6 end process;
8 clock1: process
9 begin
    clk1 <= '1';
10
11
    loop
12
      wait for (T/2);
13
      clk1 <= not clk1;</pre>
14
    end loop;
15 end process;
17 -- lazy way
18 clock2: clk2 <= not clk2 after (T/2);</pre>
```

One time stimuli can be modelled using the following expression. Note that the time is absolute.

```
1 tb_sig <= '0',
2 '1' after 20 ns,
3 '0' after 30 ns, -- 10 ns later
4 \( \langle value \rangle \) after \( \langle time \rangle ; \)</pre>
```

Repeating sequences can be created using processes.

```
1 sequence: process
2 begin
3    tb_sig <= '0';
4    wait for 20 ns;
5    tb_sig <= '1';
6    wait for 10 ns;
7    ...
8 end process;</pre>
```

For loops are also available, and can be synthesised if they run over a finite range.

#### 5.4 Assertions

Assertions are used write tests to check that a signal is in the correct state.

```
1 [label]: assert \langle condition \rangle report \langle string \rangle

\hookrightarrow severity \langle severity \rangle;
```

The report and severity are optional but strongly advised. The severity can take one of 4 values: note, warning, error, failure. Simulations can be configured to stop in when an error of the desired severity occurrs. An example:
